

Short Interpretation

The analysis indicates that several advanced economies, including Canada, Australia, France, Belgium, and Italy, experienced declines in both industry and manufacturing value added as a share of GDP between 2000 and 2024, suggesting a long-term trend of de-industrialization. Despite these declines, GDP continued to grow in most countries, reflecting a structural shift toward service-based economies rather than overall economic stagnation. Manufacturing generally declined faster than total industry in countries such as Canada and Australia, although this pattern was not universal; in countries including South Africa and Mexico, the overall industrial sector contracted more rapidly than manufacturing. Some advanced economies, particularly Germany, Denmark, and the Netherlands, maintained relatively stable or increasing manufacturing shares, highlighting stronger industrial competitiveness. Emerging economies displayed more diverse trends. China continued to industrialize, with strong growth in industry and manufacturing alongside robust GDP growth, whereas Brazil and South Africa exhibited signs of de-industrialization despite positive economic growth. Overall, the findings suggest that de-industrialization is more common in advanced economies, while emerging economies follow diverse development paths depending on their level of industrialization, economic structure, and policy environment.
